

Econ 340: Research Project Submission 2 Example
Student Name 1 and Student Name 2

I. Data and Variables Description

In this project, we study whether the ratio of students to teachers affects the performance of elementary school students. To answer this question, we use data from 420 school districts in California for the years 1998 and 1999. To measure performance, we use the average test score on reading and math (*testscr*), our dependent variable. Our primary independent variable is the student-teacher ratio (*str*).

In addition, we will also consider how the availability of computers and the percentage of students qualifying for school lunch (*meal_pct*) interact with test performance and the student-teacher ratio. To measure the availability of computers, we construct a binary variable, *high_comp_stu*, that takes the value 1 if computers per student are above the median and 0 otherwise.

To make meaningful comparisons, we limit our sample to only K-8 schools. Our final data contains 359 observations.

II. Summary Statistics

Table 1 presents the summary statistics for all our variables of interest. From this table, we can see that the mean test score for reading and math across schools is approximately 653. The lowest test score in the data is 605.5, while the highest score is 706.75. Furthermore, the median test score is 653.55, which indicates that the distribution of test scores is not skewed.

Table 1: Summary Statistics

Statistic	N	Mean	St. Dev.	Min	Median	Max
testscr	359	652.90	18.68	605.55	653.55	706.75
str	359	19.71	1.88	14.00	19.78	25.80
high_comp_stu	359	0.50	0.50	0	1	1
meal_pct	359	45.93	26.78	0.00	44.68	100.00

On average, schools have 19.71 students per teacher, with a range of student-teacher ratios varying from 14 to 25.80. This suggests that there is a notable difference in class sizes across schools. The average of the indicator for high computer availability is 0.5, showing that the number of computers is above the median for 50% of the schools. We can also see that, on average, 45.93% of students in a school qualify for school lunches, with a range of 0-100.

III. Relationship between Test Score and Student-Teacher Ratio

We start by exploring the relationship between test scores and the student-teacher ratio. Figure 1 presents a scatterplot with test scores on the y-axis and student-teacher ratio on the x-axis. From the figure, we can see that schools with a higher student-teacher ratio tend to have lower test scores and vice versa. We confirm this pattern by computing the correlation between the two variables, which is calculated to be -0.20.

Figure 1: Scatterplot for Test Score and Student-Teacher Ratio

IV. Exploring Other Factors

After examining the relationship between test scores and student-teacher ratio, we now explore how other school and student characteristics influence this relationship. Specifically, we investigate the impact of two variables: the availability of computers and the percentage of students eligible for school lunch.

Table 2 displays the correlation between these two additional variables and test scores and the student-teacher ratio. As expected, we observe a positive correlation between the availability of computers and test scores. Conversely, the correlation between computers and the student-teacher ratio is negative, suggesting that schools with higher student-teacher ratios often have fewer computers. Hence, failing to account for the number of computers may lead us to overestimate the negative impact of higher student-teacher ratios on test scores.

Table 2: Correlation Matrix

	testscr	str	meal_pct	high_comp_stu
testscr	1	-0.20	-0.86	0.23
str	-0.20	1	0.11	-0.26
meal_pct	-0.86	0.11	1	-0.19
high_comp_stu	0.23	-0.26	-0.19	1

This suggests that schools with higher student-teacher ratios may be situated in districts with limited resources, which could potentially lead to lower test scores. Consequently, neglecting to account for the percentage of students qualifying for school lunches or other markers of socioeconomic factors may result in an overestimation of the detrimental effect of student-teacher ratios on test scores.
